Cases Where ViewModel Is a Must

1. When the View Needs Data from Multiple Models

Sometimes a page needs to display data that comes from more than one model. For example, a page may need to show department information along with its students and courses. In this case, using a ViewModel helps combine the needed data from different models into one object that can be easily sent to the view.

2. Security Case

A ViewModel is important for security when the main model contains sensitive data that should not be shown to the user, such as passwords, salaries, or internal system data. By using a ViewModel, we can send only the required fields to the view and hide sensitive information, which improves the security of the application.

3. When the View Needs Custom or Calculated Data

Sometimes the view needs data that does not exist directly in the database but must be calculated or formatted. For example, displaying the department state (Main or Branch) based on the number of students. In this case, a ViewModel can include additional properties that store this calculated data and make it easier to display in the view.
